
Image Denoising

Homework n°2 - Exercises

Exercise 5.1

We denote by n the dimension of the initial image u_0 , and k the dimension of the low-scale image u_1 .

Let us explain how u_1 is obtained from u_0 .

- First, we consider the DCT transform of u_0 , denoted by $\text{DCT}_n^{\text{iso}}(u_0)$.
- Then, we pad to remove high frequencies, and we obtain $\text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0))$.
- Because we changed the size (from n to k), we have to scale the image by a factor $\frac{k}{n} = \sqrt{\frac{k \times k}{n \times n}} = \sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}}$, that is we consider $\sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}} \text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0))$.
This is what is done in Algorithm 5, in the function ExtractScale, lines 14 and 16.
- Finally, we convert back the above to an image, which means we get (by linearity of $\text{IDCT}_k^{\text{iso}}$) $\sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}} \text{IDCT}_k^{\text{iso}}(\text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0)))$.

So we have
$$u_1 = \sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}} \text{IDCT}_k^{\text{iso}}(\text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0))).$$

Since $u_0 = \tilde{u}_0 + n_0$ with $n_0 \sim \mathcal{N}(0, \sigma_0^2)$, we have $u_1 = \tilde{u}_1 + n_1$ with $n_1 \sim \mathcal{N}(0, \sigma_1^2)$, where:

$$\begin{aligned} \sigma_1^2 &= \text{Var}(n_1) \\ &= \text{Var}(u_1) \\ &= \text{Var} \left(\sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}} \text{IDCT}_k^{\text{iso}}(\text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0))) \right) \\ &= \left(\sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}} \right)^2 \text{Var}(\text{IDCT}_k^{\text{iso}}(\text{ZP}_k(\text{DCT}_n^{\text{iso}}(u_0)))) \\ &= \frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})} \sigma_0^2, \end{aligned}$$

where, for the last equality, we used the fact that DCT and IDCT preserve the variance (because they are isometries).

We therefore have $\sigma_1 = \sigma_0 \sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}}$ i.e., the noise standard deviation at the lower

scale has been multiplied by $\sqrt{\frac{\text{NUMPIX}(\text{layer})}{\text{NUMPIX}(\text{input})}}$.
